Rejection Regions and P - Values

At the $\alpha \in (0,1)$ significance level, using the test statistic TT, with observed value $TT_0 = TT(\theta = \theta_0)$, to test

$$H_0: \theta = \theta_0$$
, versus

a. $H_1: \theta < \theta_0$ (left-tailed test):

$$RR = (-\infty, tt_{\alpha}), P = P(TT < TT_0).$$

b. $H_1: \theta > \theta_0$ (right-tailed test):

$$RR = (tt_{1-\alpha}, \infty), P = P(TT > TT_0).$$

c. $H_1: \theta \neq \theta_0$ (two-tailed test):

$$RR = (-\infty, tt_{\frac{\alpha}{2}}) \cup (tt_{1-\frac{\alpha}{2}}, \infty), \ P = 2\min\{P(TT < TT_0), P(TT > TT_0)\} \Big(\stackrel{\text{sym}}{=} 2P(TT > |TT_0|) \Big).$$

- **1.** For a population mean, $\theta = \mu$,
- large sample (n > 30) or normal underlying population and σ known, $TT = \frac{X \mu}{\frac{\sigma}{\sqrt{n}}} \in N(0, 1)$; ztest
- large sample (n > 30) or normal underlying population $TT = \frac{\overline{X} \mu}{\frac{s}{\sqrt{n}}} \in T(n-1)$. ttest
- **2.** For a population variance, $\theta = \sigma^2$, for a normal underlying population, $TT = \frac{(n-1)s^2}{\sigma^2} \in \chi^2(n-1)$.
- **3.** For the difference of two population means, $\theta = \mu_1 \mu_2$, for large samples $(n_1 + n_2 > 40)$ or normal underlying populations and independent samples,

$$-\sigma_1,\sigma_2 \text{ known, } TT = \frac{\overline{X}_1 - \overline{X}_2 - (\mu_1 - \mu_2)}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}} \in N(0,1);$$

$$-\sigma_1=\sigma_2, \text{ unknown, } TT=\frac{\overline{X}_1-\overline{X}_2-(\mu_1-\mu_2)}{s_p\sqrt{\frac{1}{n_1}+\frac{1}{n_2}}}\in T(n_1+n_2-2), \text{ where } s_p^2=\frac{(n_1-1)s_1^2+(n_2-1)s_2^2}{n_1+n_2-2};$$

$$-\sigma_1 \neq \sigma_2$$
, unknown, $TT = \frac{\overline{X}_1 - \overline{X}_2 - (\mu_1 - \mu_2)}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}} \in T(n)$, with

$$\frac{1}{n} = \frac{c^2}{n_1 - 1} + \frac{(1 - c)^2}{n_2 - 1} \quad \text{and} \quad c = \frac{\frac{s_1^2}{n_1}}{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}.$$

4. For the ratio of two population variances, $\theta = \frac{\sigma_1^2}{\sigma_2^2}$, for normal underlying populations and independent samples, $TT = \frac{s_1^2/\sigma_1^2}{s_2^2/\sigma_2^2} \in F(n_1 - 1, n_2 - 1)$.
